Purpose: The pathogenesis of osteoarthritis (OA) is characterized by joint degeneration. The pro-inflammatory cytokine interleukin (IL)-1 β plays a vital role in the pathogenesis of OA by stimulation of specific signaling pathways like NF- κ B, PI3K/Akt, and MAPKs pathways. The catabolic role of growth factors in the OA may be inhibited cytokine-activated pathogen. The purpose of this study was to investigate the potential effects of insulin-like growth factor-1 (IGF-1) on IL-1 β -induced apoptosis in rabbit chondrocytes in vitro and in an in vivo rabbit knee OA model.

Methods: In the present study, the OA developed in chondrocyte with the treatment of IL-1 β and articular cartilage ruptures by removal of cartilage from the rabbit knee femoral condyle. After IGF-1 treatment, immunohistochemistry and qRT-PCR were identified OA expression with changes in MMPs (matrix metalloproteinases). The production of ROS (intracellular reactive oxygen species) in the OA was detected by flow cytometry. Further, the disease progression was microscopically investigated and pathophysiological changes were analyzed using histology. The NF- κ B, PI3K/Akt and P38 (MAPK) specific pathways that are associated with disease progression were also checked using the Western blot technique.

Results: The expression of MMPs and various apoptotic markers are down-regulated following administration of IGF-1 in a dose-dependent fashion while significantly up-regulation of TIMP-1. The results showed that higher levels of ROS were observed upon treatment of chondrocytes and chondral OA with IL-1 β . Collectively, our results indicated that IGF-1 protected NF- κ B pathway by suppression of PI3K/Akt and MAPKs specific pathways. Furthermore, the macroscopic and pathological investigation showed that it has a chondroprotective effect by the formation of hyaline cartilage.

Conclusion: Our results indicate a protective effect of IGF-1 against OA pathogenesis by inhibition of NF- κ B signaling via regulation of the MAPK and PI3K/Akt signaling pathways and prevention of apoptosis by suppression of ROS production.

Introduction

Osteoarthritis (OA) is a disorder characterized by joint pain and disability that is associated with deterioration in quality of life. Age, obesity, trauma, instability, bone mass, joint injury and developmental disease are common causes of OA.¹ Chondrocytes play an important role in chondral osteogenesis and cartilage regeneration by synthesize extracellular matrix components, such as proteoglycans and

collagen.² The destructive structure and damaged articular cartilage is very slow healing because of cartilage non-innervated and non-vascular tissue.³

Inflammatory cytokines have a principle role in the pathogenesis of OA.⁴ Following a cartilage injury, the stimulation of catabolic influences such as post-inflammatory cytokines encompassing tumor necrosis factor α (TNF- α) and IL-1 β are involved in the development of OA.⁵ Chondrocytes exposed to TNF- α and IL-1 β are key mediators to release matrix metalloproteinases (MMPs), and inhibits the synthesis of extracellular matrix proteins in chondrocytes which are responsible for the degeneration of articular cartilage.^{6–8} The balance among MMPs and TIMPs (tissue inhibitors of metalloproteinases) are important for the regulation of pathogenesis of Matrix metalloproteinases like MMP-1 (interstitial collagenase), MMP-3 (stromelysin-1) and MMP-13 (collagenase 3) plays an essential part in osteoarthritis based on their capability to cleave components of the ECM in articular cartilage.^{9–11} At the time of osteoarthritis, several catabolic signaling pathways have also been exposed to orchestrate the expression of matrix metalloproteinases, containing NF- κ B, phosphatidylinositol 3-kinase (PI3K)/Protein kinase B (AKT) and MAPKs (mitogen-activated protein kinases) signaling pathways.^{12,13} The activated MAP kinases stimulate transcriptional regulatory proteins and other kinases of protein and which is enhanced the inflammatory cytokine such as TNF- α , IL-1, and MMPs production.¹⁴ The cytokines like IL-1 β lead to activate PI3K/AKT signaling when it binds to the cell surface receptor. Upon stimulation, the PI3K produces AKT phosphorylation which has exposed to have a synergistic impact on NF- κ B signaling. The MMPs will upregulation during the activation of PI3K/AKT signaling.¹⁵ The transcription factor of NF- κ B shows a significant role in osteoarthritis pathogenesis and it stimulated by cytokine of pro-inflammatory when ECM destruction.¹⁶

Currently, steroidal and non-steroidal anti-inflammatory drugs (NSAIDs) are used for the treatment of OA, but these treatments fail to reverse disease progression.^{17,18} Many methods like Mosaicplasty, autologous chondrocyte implantation, chondrocyte transplantation and micro fracture have been reported to relieve inflammation and recover damage of cartilage.^{19,20} A universally accepted technique for repairing damage to cartilage has not been identified. The significant cellular progress, such as survival, growth, differentiation and antagonize has the effect of inflammatory intermediaries by the influence of anabolic growth factors.²¹

Insulin-like growth factor-1 (IGF-1) is the leading anabolic growth factor in cartilage and is important for structural maintenance via stimulation of cartilage matrix molecules.^{22–25} During cartilage destruction, pro-inflammatory cytokines like IL-1 β have been shown to have catabolic effects.²⁶ IGF-1 plays a primary role in articular cartilage, where it balances the synthesis of type II collagen and proteoglycans for chondrocyte regulation.^{27,28} Recent studies revealed that IGF-1 protects chondrocytes from apoptosis.^{29–31} The impact of IGF-1 on PI3K/AKT, MAPK, and NF- κ B signaling pathway has not been clearly elucidated. For this reason, we are interested in investigating the role of IGF-1 in these signaling pathways in chondrocytes (in vitro) and the rabbit model during OA progression. The aim of this study is to assess the effect of intra-articular injection of IGF-1 on the regeneration of chondrocytes in the femoral condyle and the anti-apoptotic effect of IGF-1 via downregulation of pro-inflammatory cytokine signaling in articular cartilage in OA.

Materials and Methods

Animal Study

New Zealand female white rabbits (12 weeks old, weighing 3.5 ± 0.2 kg, N=40) were obtained from Koatech (Seoul, Korea). The animals were fed a normal diet and given water ad libitum. The animal room was maintained at $24 \pm 2^\circ\text{C}$ with air conditioning under a 12 h light/12 h dark cycle. All surgical experiments were approved by the Chonbuk National University Animal Ethical Care and Use Committee (CBNU-2018-112). The guideline for laboratory animals of Internal Animal Care and Use Committee (IACUC) on Chonbuk National University.

Chondrocyte Isolation and Culture

Rabbit articular chondrocytes were collected from the knee cartilage of 12-week-old New Zealand female white rabbits. Briefly, cartilage slices were digested with 0.25% trypsin (Lonza, Belgium) for 30 minutes and then incubated for 4–6 h in Dulbecco's modified Eagle's medium/F-12 (DMEM/F-12; Gibco, Grand Island, NY) with 0.2% type II collagenase (Gibco, USA) at 37°C in a shaking incubator. The chondrocytes were re-suspended after centrifugation and cultured in 25 cm^2 culture flasks in complete DMEM/F12 with 10% FBS (Gibco, USA) and 1% antibiotic/antimycotic solution (Sigma-Aldrich, USA) in 5% CO_2 at 37°C . The culture media was changed every other day. For in vivo studies, the cells were stored at -80°C for later use.

Experimental Design of in vitro and in vivo Studies

To investigate the effect of IGF-1 on IL-1 β -induced chondrocytes, cells were plated in a 6-well plate at a density of 5×10^6 cells/well. The cells were pretreated for 1 h with various concentrations of IGF-1 (10, 30, and 100 ng/mL) before the addition of IL-1 β (10 ng/mL) and further incubation for 24 h. Diclofenac (50 μ g/mL) served as a positive control. For the in vivo study, the rabbits were randomly assigned to six groups ($n = 6$) as follows: 1) normal control (N/C): articular cartilage was exposed and closed; 2) chondrectomy (Ch.tomy): articular cartilage was damaged but received no treatment; 3) 0.1 IGF-1: treated with 0.1 μ g/kg IGF-1 for 10 days (intra-articularly); 4) 0.3 IGF-1: treated with 0.3 μ g/kg IGF-1 for 10 days (intra-articularly); 5) 1.0 IGF-1: treated with 1.0 μ g/kg IGF-1 for 10 days (intra-articularly); and 6) diclofenac (positive control): treated with 5 mg/kg diclofenac for 10 days (intramuscularly).

In detail, after sedation, the animals were placed on the operating table in a supine position. The animals were kept anesthetized under 3% isoflurane in oxygen during the surgery by a face mask. Before surgery, the right knee was sterilized with 70% alcohol, and 10% betadine solution. After exposing the right knee femoral condyle with a medial para-patellar incision, cartilage was removed using a surgical blade from the trochlear surface. The skin and tissues were sutured with polyglactin 2/0 suture material. All treatments commenced 2 weeks after surgery.

Real-Time PCR

To quantify mRNA levels of OA and apoptosis-related gene expression, total RNA was extracted from the cells for in vitro and cartilage for in vivo according to the manufacturer's instructions (iNtRON Biotechnology, South Korea). cDNA was synthesized from 500 ng of

total RNA as a template using a cDNA synthesis kit (iNtRON Biotechnology, South Korea). Gene expression was quantified using SYBR green real-time PCR master mix (TOYOBO, Japan) and amplified under the following conditions: 2 min at 95°C, 20 s at 95°C, and 20 s at 58°C, for 40 cycles. The primer sequences used for PCR are shown in Table 1. Expression was evaluated in triplicate for each gene to reduce processing error. Using the $2^{-\Delta\Delta Ct}$ method, relative gene expression was evaluated by normalizing target gene expression to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) expression.

Reactive Oxygen Species

Reactive oxygen species (ROS) production was analyzed with a ROS detection kit with CellROX Green reagent (C10444, Invitrogen) from Life Technologies (made in the USA) according to the manufacturer's instructions. Chondrocytes were treated with various doses of IGF-1 for 1 h, stimulated with IL-1 β for 24 h, then washed twice with PBS and incubated with 5 μ M CellROX Green reagent in PBS at 37°C for 60 min in the dark. After washing with PBS, fluorescence was measured immediately using flow cytometry (BD Accuri). Chondrocytes from rabbits after sacrifice at 4 and 8 weeks were used for in vivo analysis.

Macroscopic Assessment

The depth of destruction in articular cartilage was evaluated according to the measures described by Pelletier et al³² using a four-point scale (0 = normal-appearing surface, 1 = negligible fibrillation or a minor yellowish discoloration of the surface, 2 = destruction spread out into the superficial or central layers only, 3 = destruction that spread into the deep layers, and 4 = destruction that spread to the subchondral bone). After 4 and 8 weeks, the animals were sacrificed by an overdose of sodium pentobarbital (IV) and the articular cartilage on the

femoral condyles in the right knee joint was opened for macroscopic evaluation. A greater score indicates more damage to the cartilage.

Histological Findings

For histological study after macroscopic observation, cartilage specimens from the destructive femoral area were fixed in a 10% buffered formalin solution (Sigma-Aldrich, USA) and decalcified with 8% formic acid and 8% HCl. Cartilage specimens were embedded in paraffin and sample sliced into 5- μ m sections. Hematoxylin-eosin (HE, (Sigma-Aldrich, USA) and Masson (Scyteck Lab.USA) stain Study after Paraffin specimens were dehydration and for glycosaminoglycan (GAG) secretion bearings by safranin O (Sigma, USA). According to Mankin et al, the rigorousness of the OA destruction was categorized using the histologic standards (Table 2) based on structural variations (scale range 0–6), cellular variations (scale range 0–3), damage of safranin O staining (scale range 0–4) and tidemark integrity (scale range 0–1) by 3 independent researchers.³³

To carry out the immunohistochemical analysis, MMP-1 expression was measured by using vectastain ABC kit (Vector Lab.In., USA) according to the manufacturer's protocol. After de-paraffin Cartilage specimens and Cells (in vitro) were washed in PBS and for deactivating endogenous peroxidase action by the use of 3% Hydrogen peroxide (H₂O₂) for 20 min

at room temperature with shaking. After blocked primary antibody (dilution 1:150), were incubated overnight at 4°C and then biotinylated second antibody horseradish peroxidase incubation 1:20 hours at RT. Afterward, before counterstaining with hematoxylin the specimens and cells were visualized until brown color with DAB kit (Thermo Scientific, USA) at dark condition. Eventually, cells were serially dehydrated and mounted. The intensity of MMP-1 staining and images were observed with an inverted contrast microscope (Zeiss Corporation, Germany) at a fixed 200x magnification.

Western Blotting

Proteins were extracted from chondrocyte (in vitro) and cartilage (in vivo) with cell lysis buffer (Pro-Prep, Intron Biotechnology, Korea) and protein concentration was measured using a BCA kit (Thermo Scientific, USA). The PVDF membrane that contained the protein was blocked with 1% (w/v) skim milk in Tris-buffered saline with Tween-20 (TBST) and then incubated overnight with primary antibodies against NF- κ B (1:500), Akt (1:500), p-Akt (1:1000) (Abcam, UK), P-p65 (1:1000), P38 (1:1000), and p-P38 (1:800) (Cell Signaling, MA, USA) at 4°C. β -actin was used as a loading control. HRP-conjugated secondary antibody (Cell Signaling, MA, USA) was then added for 2 h, and the membrane was washed with PBS. Specific proteins were identified on the immunoblots with Lumi pico solution (DoGen, Korea) and images of the blots were taken with a ImageQuant LAS-500 image analyzer (GE Healthcare, Sweden). Band quantification and analysis were performed using Image J software (ver. 1.49).

Statistical Analysis

Data are expressed as mean \pm standard deviation. Statistical significance was assessed using analysis of variance (ANOVA) followed by Tukey's multiple comparison tests. Statistical significance was defined as $p < 0.05$. All in vitro experiments were performed in triplicate and the results are mean values of three independent experiments.

Results

Impact of IGF-I on Chondrocyte Immunohistochemistry in vitro

MMP1 protein levels in chondrocytes following various treatments were analyzed using immunohistochemical techniques. The results revealed that IL-1 β treatment significantly upregulated the expression of MMP1 (observed as intense staining) compared with control treatment in

chondrocytes. However, administration of IGF-1 significantly reduced MMP1 levels dose-dependently (Figure 1A).

Impact of IGF-I on TIMP-I and MMPs in vitro

After treatment with IGF-1, the gene-level of TIMP-1, MMP-13, MMP-3, and MMP-1 were detected in chondrocytes by performed qRT-PCR. IGF-1 treatment increased TIMP-1 gene expression and protected high levels of MMP-13, MMP-3, and MMP-1 in chondrocytes dose-dependently. On the other hand, chondrocytes stimulated with IL-1 β exhibited only TIMP-1 gene downregulation and enhancement of MMP-13, MMP-3, and MMP-1 gene expression compared with normal control (Figure 1B). MMP1 protein expression levels were also in line with these results.

Impact of IGF-I on ROS Production in vitro

Reactive oxygen species (ROS) have a vital role in the inflammatory process. The effect of IGF-1 on intracellular

ROS secretion in IL-1 β -induced chondrocytes was investigated. Intracellular ROS generation was greater in the IL-1 β treated group ($76.7 \pm 6.2\%$). IGF-1 treatment dose-dependently downregulated intracellular ROS secretion by $54.2 \pm 3.6\%$, $46.3 \pm 2.3\%$, and $38.1 \pm 1.9\%$ at doses of IGF-1 10, 30, and 100 ng/mL respectively (Figure 1C).

Impact of IGF-I on PI3K/Akt, NF- κ B, and MAPK Signaling in vitro

To examine whether IGF-1 inhibits IL-1 β -induced damage in chondrocytes, we investigated the activity of the PI3K/Akt, NF- κ B, and MAPK signaling pathways using Western blot analysis. IGF-1 dose-dependently down-regulated p-Akt/Akt, P-p65/NF- κ B, and p-P38/P38, whereas IL-1 β treatment up-regulated the proteins (Figure 2A and B).

Impact of IGF-I on TNF- α , Caspase-3 and Bax in vitro

Additional examination exposed that the pro-inflammatory factor TNF- α and the pro-apoptotic genes caspase 3 and

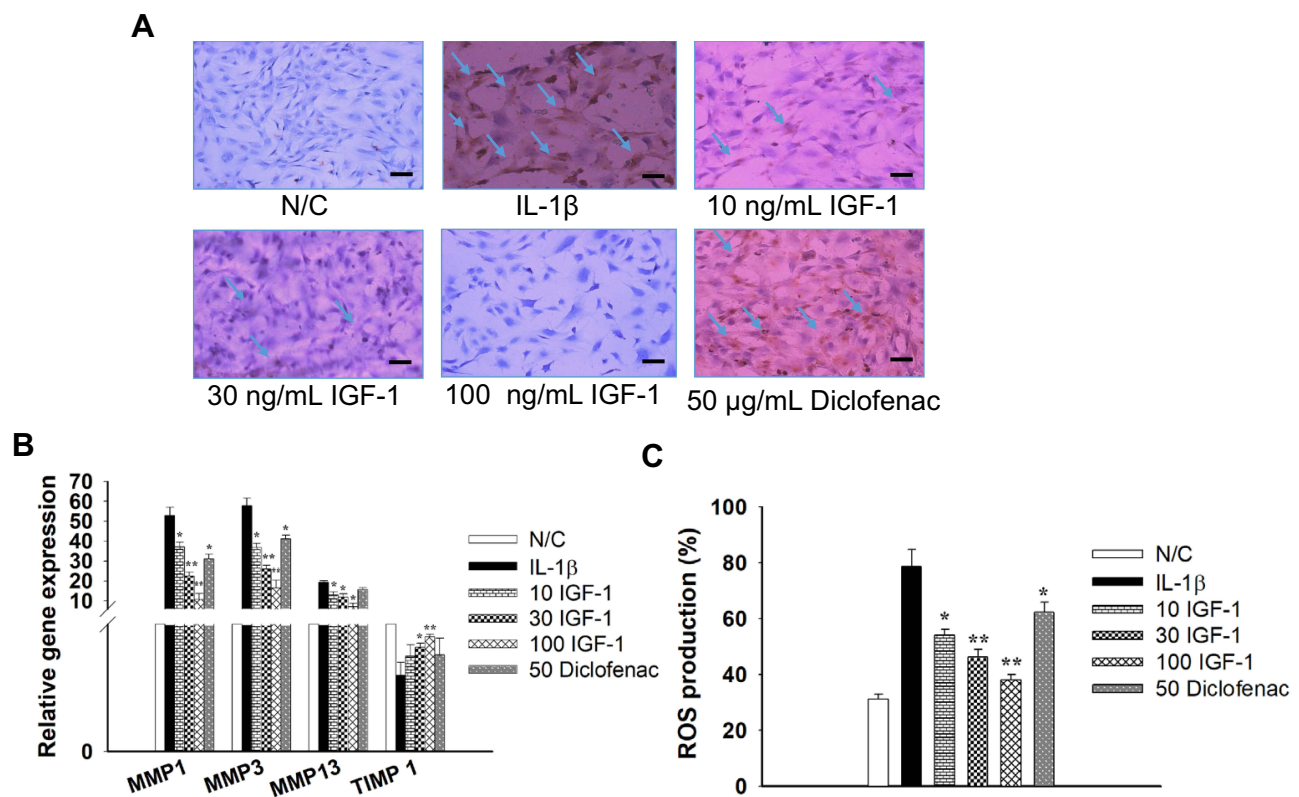

Figure 1 Effects of IGF-I on Chondrocytes during the development of OA induced by IL-1 β 10 ng/mL, (A) immunohistochemistry staining for the existence of MMP-1 in vitro ($\times 200$, Scale bar = 200 μ m), (B) Real-time PCR on mRNA for MMP-13, MMP-3, MMP-1 and TIMP-1, and (C) quantitative histogram of ROS production. Here, N/C= Normal control, IL-1 β = 10 ng/mL IL-1 β , 10 IGF-1= 10 ng/mL IGF-1, 30 IGF-1= 30 ng/mL IGF-1, 100 IGF-1= 100 ng/mL IGF-1, and 50 Diclofenac= 50 μ g/mL Diclofenac. Values are the mean \pm SD. * p < 0.05, and ** p < 0.01.

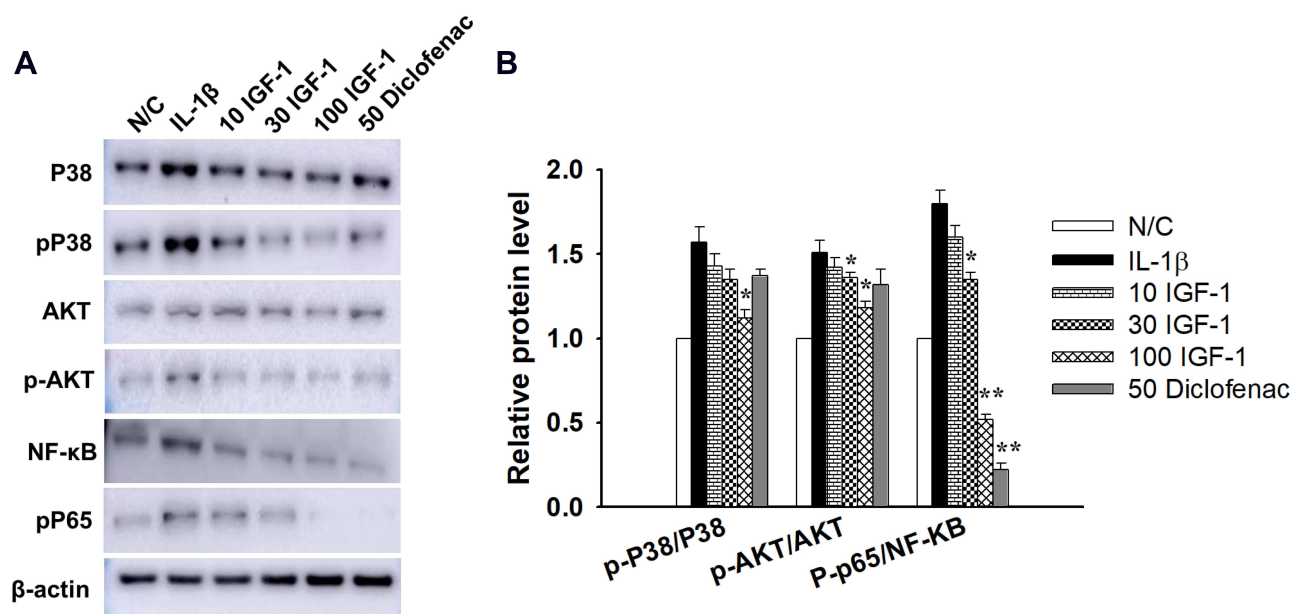

Figure 2 Effects of IGF-1 on primary chondrocytes during IL-1 β stimulated specific signaling pathways, (A) Western blotting for the expression of p-P38/P38, p-Akt/Akt, P-p65/NF- κ B and (B) quantitative histogram in vitro. Values are the mean \pm SD. * $p < 0.05$, and ** $p < 0.01$.

bax were increased in IL-1 β -stimulated chondrocytes. On the other hand, IGF-1 dose-dependently downregulated gene expression of TNF- α , caspase 3, and bax (Figure 3A–C). This result indicates that IGF-1 prevents pro-inflammatory and pro-apoptotic activity in vitro.

Macroscopic Evaluation in vivo

A protective effect of IGF-1 was observed on the articular cartilage defects induced in OA rabbits. After 4 and 8 weeks, the OA group had damage to the cartilage characterized by a highly irregular surface; the surface area that went from whitish to reddish increased over time in the middle of the femoral condyle. By contrast, the normal control group had macroscopically regular cartilage with a smooth surface without any defects in the femoral condyle. The group that received IGF-1 showed recovery defect trochlear surface by fibrous tissue with a thin layer at 4 weeks and almost repaired at 8 weeks with proliferative fibrous tissue that was evident in the OA group. IGF-1 was associated with the new formation of hyaline cartilage such as tissue in a dose-dependent manner (Figure 4A and B).

Intracellular ROS Production in vivo

The effect of IGF-1 on intracellular ROS production in chondrocytes with osteoarthritis was investigated. Using CellROX Green reagent from a ROS detection kit, ROS secretion was analyzed after IGF-1 treatment in articular

cartilage at 4 and 8 weeks. Intracellular ROS generation decreased after IGF-1 treatment than cartilage defect animals in a time- and dose-dependent manner (Figure 4C).

MMPs and TIMP-1 Gene Expression in vivo

We next assessed the effects of IGF-1 on the expression of TIMP-1 and matrix metalloproteinases (MMPs) in femoral condyle cartilage. qRT-PCR was performed to detect the gene levels of TIMP-1, MMP-13, MMP-3, and MMP-1 in the defective cartilage after treatment with IGF-1 at 4 and 8 weeks. The IGF-1 group showed significant up-regulation of TIMP-1 gene expression and downregulation of MMP-13, MMP-3, and MMP-1 expression compared with the OA control group. The OA group was shown to have reduced TIMP-1 gene expression and increased MMP-13, MMP-3, and MMP-1 levels (Figure 5A and B). Our results suggest that IGF-1 may prevent the progression of osteoarthritis by decreasing the MMPs and increasing the TIMP-1 genes expression.

TNF- α , Caspase-3 and Bax in vivo

Additional examination revealed that TNF- α (a pro-inflammatory factor) gene expression and the pro-apoptotic genes caspase 3 and bax were increased in the cartilage defect group. On the other hand, IGF-1 treatment dose-dependently downregulated the expression of the TNF- α , caspase 3, and bax genes (Figure 5C–E). This result indicates

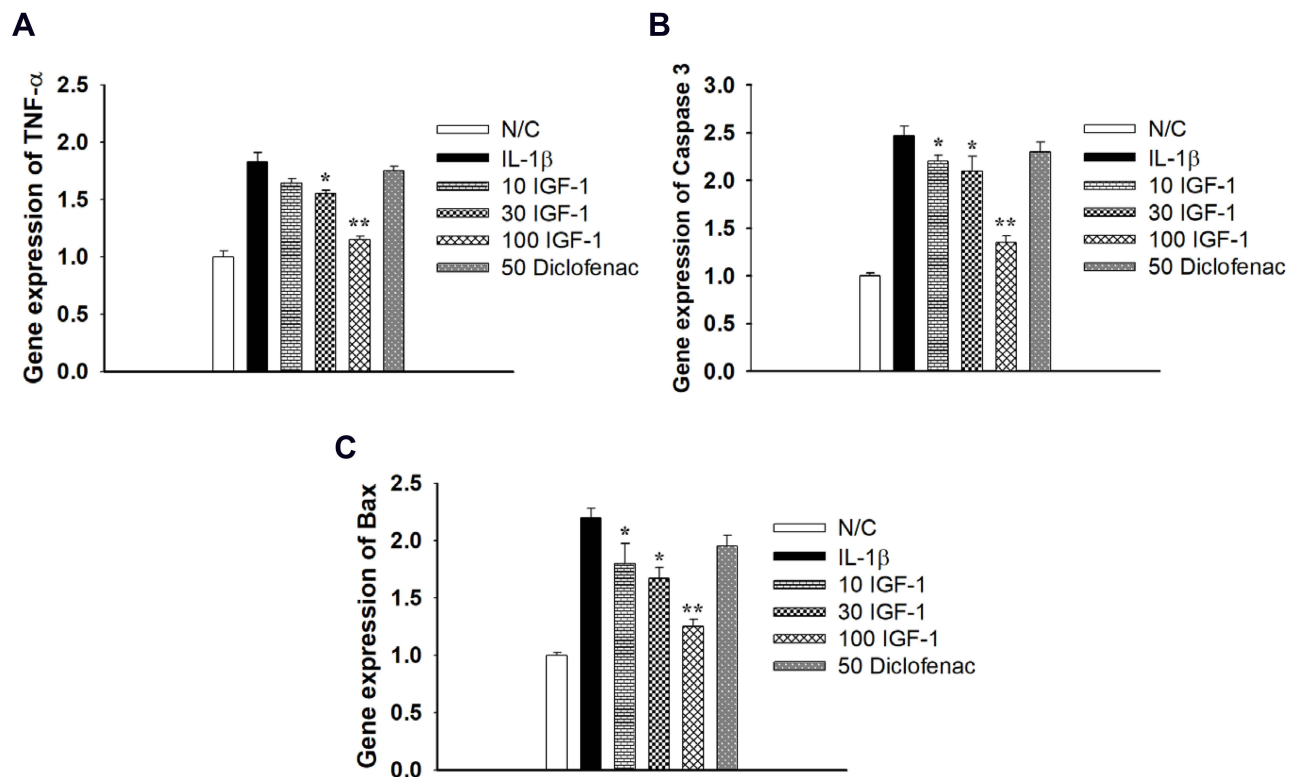

Figure 3 Effects of IGF-1 on IL-1 β stimulated apoptosis in monolayer Chondrocytes in gene level of (A) TNF- α , (B) Caspase 3 and (C) Bax gene expression in vitro. Values are the mean \pm SD. * p < 0.05, and ** p < 0.01.

that IGF-1 prevents pro-inflammatory and pro-apoptotic activity in vivo in the OA rabbit model, which is similar to the in vitro results.

PI3K/Akt, NF- κ B, and MAPK Signaling in vivo

We observed in vivo protein expression of the PI3K/Akt, NF- κ B, and MAPK signaling pathways. The OA control group was shown to have higher expression of P-p65/ NF- κ B, p-P38/P38, and p-Akt/Akt when compared to the normal control group, and IGF-1 dose-dependently down-regulated P-p65/NF- κ B, p-P38/P38, and p-Akt/Akt protein levels (Figure 6A–D).

Histological Findings in vivo

Abnormality of femoral condyle cartilage was evaluated by examining histological changes in the articular cartilage after IGF-1 treatment at 4 and 8 weeks. We considered the loss of glycosaminoglycan (GAG), lesions, scraping of the surface, and regeneration of new tissue. The OA control

group had serious defects after 8 weeks compared to 4 weeks, with degraded condyle cartilage from the femoral trochlear surface, reduced chondrocytes (Figure 7A), and lesions GAG (Figure 7B) and Masson's trichrome staining also showed collagen damage in the articular cartilage area (Figure 7C). On the other hand, the IGF-1 group was protected from cartilage destruction; it had decreased chondrocyte-related irregularities, healthier expression of MMPs, and notably reduced condyle cartilage damage. The IGF-1 treated group was also observed to have new fibrous tissue in the defect area, as in the normal control group, and more collagen formation in the articular cartilage area, which was similar to the normal control on macroscopic investigation.

Immunohistochemistry Analysis for MMP-1 in vivo

MMP-1 plays an important role in the development of osteoarthritis in condyle cartilage. In normal animals, fewer MMP-1-positive cells were observed in the

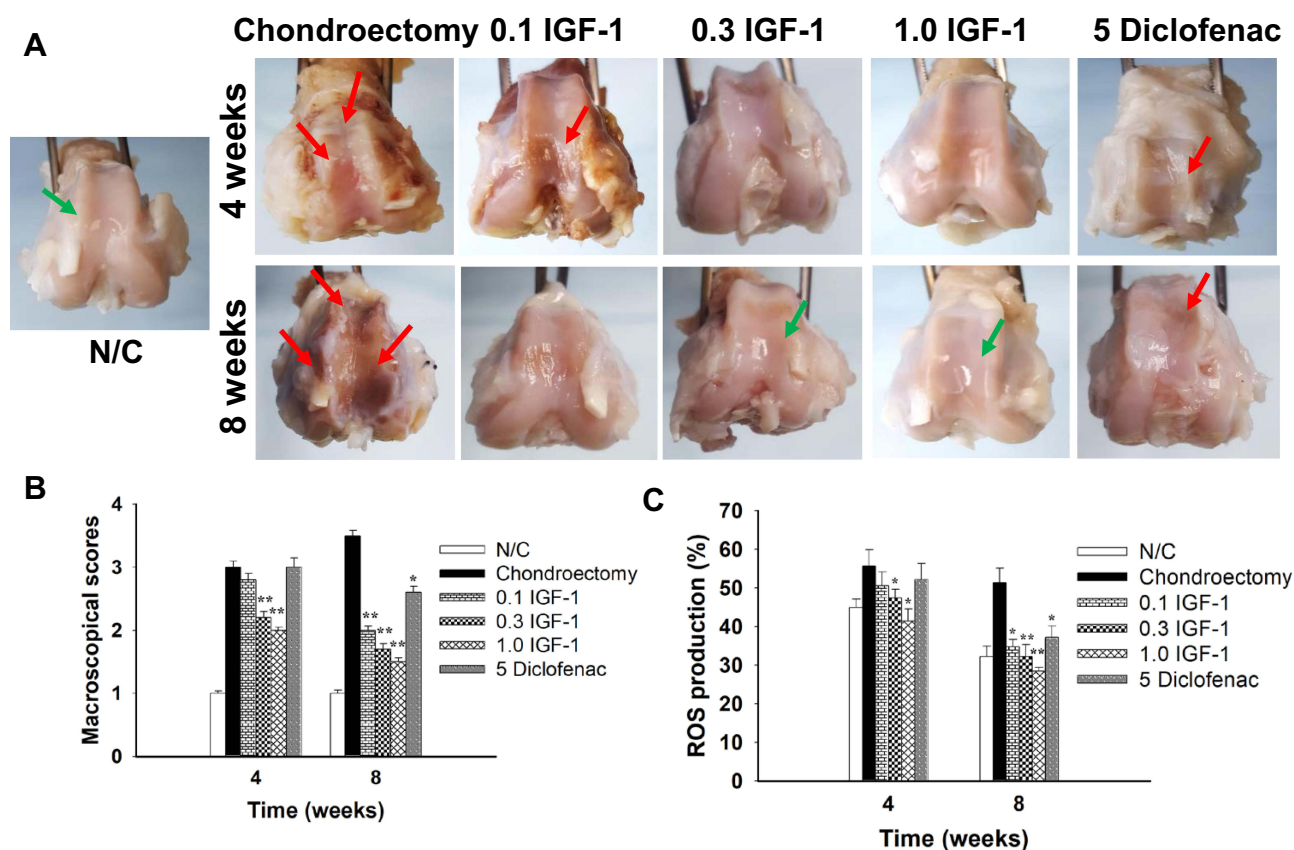

Figure 4 Effects of IGF-I on (A) macroscopic pictures and (B) macroscopic scores of rabbit's femoral condyles from cartilage damage after treatment with IGF-I at 4 and 8 weeks and (C) quantitative histogram of ROS production in femoral condyles at 4 and 8 weeks in vivo. The Red arrow indicated articular cartilage destruction and the green arrow indicated reconstruction of femoral condyle surface by formation of new fibrous tissue. Here, N/C= Normal control, 0.1 IGF-I= 100 ng/mL IGF-I, 0.3 IGF-I= 300 ng/mL IGF-I, 1.0 IGF-I= 1 μ g/mL IGF-I, and 5 Diclofenac= 5 mg/mL Diclofenac. Values are the mean \pm SD. * p < 0.05, and ** p < 0.01.

superficial and middle cartilage layer then were seen in the defect animals. In contrast, the disease control rabbit's condyle cartilage showed a significant number of MMP-1-positive cells. Conversely, IGF-1 treatment was associated with less MMP-1-positive staining than the defect group in a dose-dependent manner and recovered from cartilage destruction (Figure 7D).

Discussion

In osteoarthritis, drug management is the first choice for treatment. IGF-1 has been shown to improve the renovation of tissue development. It helps in the recovery of large cartilage defects and aids in maintaining the balance between type II collagen and proteoglycans in the articular cartilage.³⁴ IGF-1 exerts anti-apoptotic and anti-inflammatory effects in primary chondrocytes via regulation of the IL-1β cellular response and NF-κB signaling pathway.³⁵ Many inflammatory diseases like osteoarthritis involve IL-1β, which is known to stimulate TIMP-1 and MMPs in the articular cartilage in vitro. Two main families of enzymes are leading

degenerative alterations in OA: MMPs, which facilitate type II collagen and matrix components of degeneration and TIMPs, which maintenance the activity of enzymes.³⁶ Different MMPs subtypes are playing various roles in different stages of articular cartilage degradation during OA pathogen. The MMP-1 expression is severely enhanced in response to stimulation of TNF-α and interleukin (IL)-1; it reduces collagen in the ECM and causes cartilage destruction, playing a significant role in the OA disease process.³⁷

MMP-13, a biochemical marker of collagenase for cartilage erosion and during the early stages of OA found in a high level in the cartilage matrix.^{38,39} TIMP-1 not only prevents the activated MMPs, but it also inhibits and delays the prototype of MMPs enzyme from changing into active types.⁴⁰ Our experimental study revealed that IGF-1 protected against IL-1β-mediated chondrocyte disruption by preventing expression of MMPs, such as MMP-13, MMP-3, and MMP-1 and enhancing TIMPs in vitro (Figure 1B). The results suggested that IGF-1 is involved in the prevention of chondrocyte-related pathological disorders by protecting

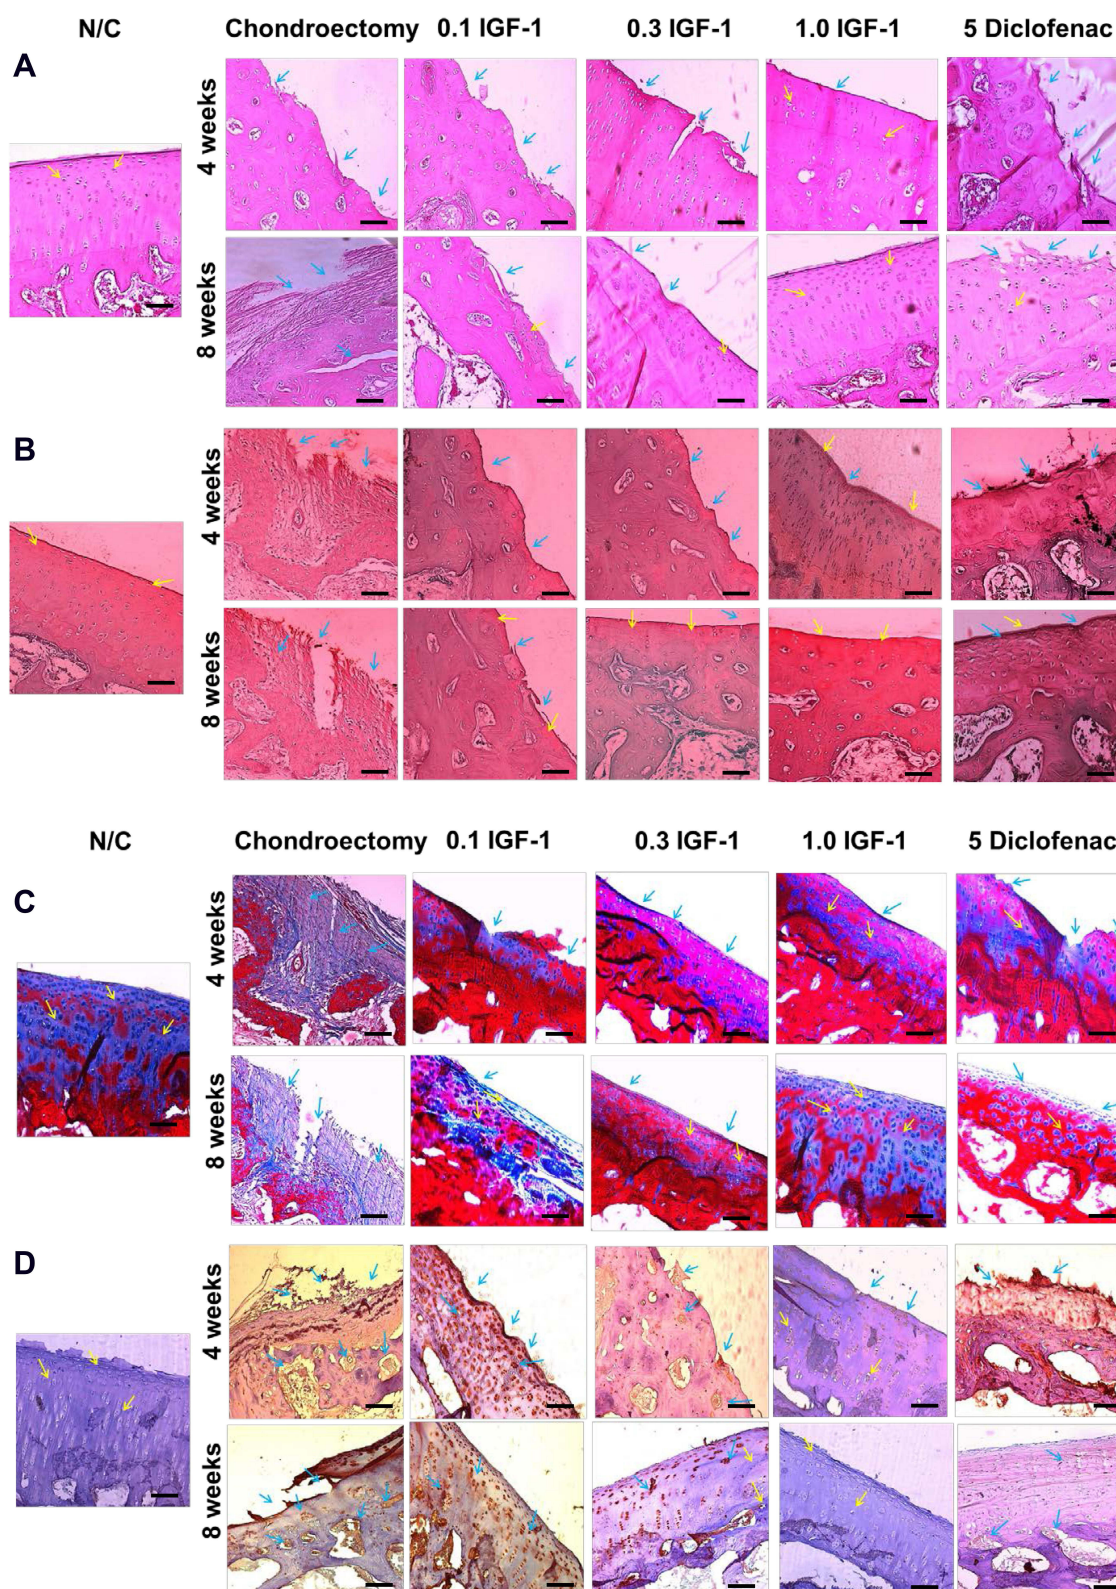

Figure 7 Effects of IGF-I on (A) hematoxylin-eosin staining (B) safranin O (C) masson's trichrome staining for the existence of the cartilage during the OA in rabbit femoral condyle after treatment of at 4 and 8 weeks and (D) immunohistochemistry staining for the existence of MMP-I in the cartilage at 4 and 8 weeks in vivo ($\times 200$, scale bar = 200 μm). Yellow arrow indicated chondrocyte cell and blue arrow indicated erosion of condyle and positive MMP-I (IHC).

from IL-1 β -mediated MMP expression, which is why we were inspired to perform our *in vivo* study. As we demonstrated, IGF-1 treatment allowed the cartilage to recover from structural damage dose- and time-dependently, thereby ameliorating OA progression, as shown by the histological study and the macroscopic appearance of the cartilage (Figures 4A, B and 7A–C, and Supplementary Figure 2). However, after receiving the IGF-1, more chondrocytes (H/E), collagen (masson's stain) and proteoglycans (safranin O stain) were observed in the defect area at 8 weeks than 4 weeks by contrast the defect group show only a few cells over the time duration. So the IGF-1 showed the chondroprotective effect against articular cartilage degradation by regulation of collagen, proteoglycan and produce hyaline cartilage. After IL-1 β induced OA in chondrocyte and cartilage rupture, the positive MMP-1 cells expressed high in the OA group than the normal control group and more proportion MMP-1 positive cells in 8 weeks than 4 weeks in particular cartilage ruptures group which means more collagen fibers decline and cartilage degradation. But after IGF-1 treatment in both *in vitro* and *in vivo* the MMP-1 positive cells significantly lower than the OA group in the dose and time-dependent (Figures 1A and 7D).

The OA-specific RNA component TIMP-1 was up-regulated and MMP-1, MMP-3 and MMP-13 levels were down-regulated in rabbits following IGF-1 administration. This evidence strengthens the notion that IGF-1 protects against cartilage defects in the OA model (Figure 5A and B). These studies are consistent with our *in vitro* investigational findings (Figure 1B). So, the current *in vitro* and *in vivo* results point to a role for IGF-1 in the prevention of chondrocyte degradation in articular cartilage. Various signaling pathways, such as the PI3K/Akt, NF- κ B, and MAPK pathways, have important roles in the metabolic and biomechanical pathways associated with the pathogenesis of OA, and IGF-1 has been shown to have anti-arthritis activity via PI3K/Akt, NF- κ B, and MAPK signaling.^{13,41} OA-related pathogenesis is majorly orchestrated by NF- κ B signaling pathway, and several other studies have also shown that the pathogenesis is also mediated by PI3K/AKT signaling via pro-inflammatory cytokines like IL-1 β . Upon binding of IL-1 β to its receptor, the membrane protein PI3K induces the phosphorylation of AKT and found to have synergistic effect on NF- κ B signaling.^{15,35} Our experimental data showed that IGF-1 significantly inhibited the stimulation of NF- κ B, as demonstrated by the reduction in NF- κ B expression both *in vitro* and *in vivo* (Figures 2A, B and 6A–D). These results

suggest that IGF-1 may decrease MMP expression by inhibiting the NF- κ B signaling pathway.

Pro-inflammatory cytokines such as TNF- α and IL-1 have been associated with the pathogenesis of OA via activation of the P38 (MAPK) intracellular signaling pathway.^{42–44} Phosphorylation of MAPKs such as p38 and ERK is known to be upregulated in arthritis when compared to normal cartilage.⁴⁵ Our results showed that IGF-1 administration significantly decreases P38 levels in an osteoarthritis animal model as well as in chondrocytes dose-dependently. Our findings clearly indicate that IGF-1 plays a vital role in the MAPK signaling pathway via regulation of P38 to prevent OA. The PI3K/AKT signaling pathway also plays a major role in OA. Phosphorylated Akt and PI3K act as persistence signals in TNF- α -associated apoptosis.⁴⁶ Our experimental data show that IGF-1 administration down-regulated p-AKT expression in a dose-dependent manner, whereas IL-1 β treatment up-regulated the expression of p-AKT *in vitro*. Furthermore, a cartilage damage model was also shown to have upregulation of p-AKT (Figures 2A, B and 6A–D). Therefore, our results indicate that IGF-1 protects against the progression of inflammatory intermediaries in OA which are involved in moderate suppression of MAPK cascades or PI3K/AKT signaling, and thereby inhibits the activation of NF- κ B. A scheme of diagram showed that anti-osteoarthritis effect of IGF-1 (Figure 8). Apoptosis may involve to the loss of chondrocyte and following degeneration of cartilage.³¹ The family of caspases that are dangerous mediators of the apoptotic pathway. The Previous study revealed that IGF-1 prevents chondrocytes apoptosis following cartilage damage.³⁰ Our study also showed that IGF-1 prevents cartilage degradation and apoptosis with significant anabolic growth function (Figures 3A–C and 5C–E). Chondrocyte apoptosis in the articular cartilage owing to intracellular ROS facilitate degradation and damage of the ECM.^{47,48} ROS-related cell death is inhibited in chondrocytes by IGF-1, which rescues the articular cartilage from ROS-stimulated cytotoxicity.⁴⁹ Our investigational study agrees with these findings. Furthermore, these results show that IGF-1 administration significantly reduced ROS production in chondrocytes *in vitro* and *in vivo* (Figures 1C and 4C) and annexin V /PI results showed that IGF-1 inhibits IL-1 β induced apoptosis in chondrocytes (Supplementary Figure 1).

Conclusion

In conclusion, we established the healing effects of IGF-1 in chondrocytes and a rabbit model against osteoarthritis. IGF-1 inhibited the NF- κ B, p38 (MAPK), and PI3K/AKT

Figure 8 An overall schematic diagram of this study clearly indicates that IGF-1 inhibits osteoarthritis activity via the PI3K/Akt, NF- κ B, and MAPK signaling pathways. (| indicate inhibitory pathways, \rightarrow indicate stimulatory pathways).

signaling pathways, thereby preventing MMPs expression during OA pathogen, and also balanced collagen type II and proteoglycan and formation of hyaline cartilage. Therefore, in articular cartilage lesions, Intra-articular injection of IGF-1 leading a better tactic for effective and efficient therapy. So, our study revealed that IGF-1 could be a potential therapeutic mediator for the management of cartilage damage related to OA. However, our initial finding only on animal and cell levels of anti-OA, further needed to clinical implementation evaluation.

Journal of Inflammation Research

Dovepress

Publish your work in this journal

The Journal of Inflammation Research is an international, peer-reviewed open-access journal that welcomes laboratory and clinical findings on the molecular basis, cell biology and pharmacology of inflammation including original research, reviews, symposium reports, hypothesis formation and commentaries on: acute/chronic inflammation; mediators of inflammation; cellular processes; molecular

mechanisms; pharmacology and novel anti-inflammatory drugs; clinical conditions involving inflammation. The manuscript management system is completely online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-inflammation-research-journal>
